European Code to good practice for the industrial manufacture of safe feed ingredients

Sector reference document on the manufacturing of safe feed ingredients from biodiesel processing

Version 2.0

Changes are highlighted in grey
Sectors covered by the European Code

The following sector specific sector documents have been developed by the respective European sector organisations in cooperation with EFISC:

- **Starch Europe**  Sector reference document on the manufacturing of safe feed ingredients from starch processing
- **FEDIOL**  Sector reference document on the manufacturing of safe feed ingredients from oilseed crushing and vegetable oil refining
- **EBB**  Sector reference document on the manufacturing of safe feed ingredients from Biodiesel processing

This European Code is open to other manufacturers producing feed ingredients by the development of a sector specific document.

Effective from: 22 March 2017

EFISC Code - Sector reference document on the manufacturing of safe feed ingredients from biodiesel processing, version 2.0
1. Introduction

The members of the European Biodiesel Board (hereinafter referred to as EBB) produce besides biodiesel, glycerine for animal feeding and for technical purposes. The EBB counts nearly 80 member companies and associations located in 21 EU Member States.

EBB members are committed to manufacture safe feed ingredients and to demonstrate their compliance to European health and safety requirements. In particular in the frame of the Feed Hygiene Regulation 183/2005/EC as well as within the Catalogue of Feed Material (Regulation 68/2013/EU).

Biodiesel is a renewable fuel, providing a sustainable alternative to fossil fuels. In addition to reducing greenhouse gas emissions in European transportation, biodiesel provides extensive amounts of glycerine used for animal feed and other by-products, used for technical purposes.

The following document intends to support biodiesel facilities in delivering safe feed ingredients. The EBB has conducted risk assessments of the chain of feed materials from the main incoming materials processed by its industry. These assessments offer a tool to the biodiesel manufacturer for the evaluation of their own feed safety management system. They also support these manufacturers in their dialogue on chain control with their customers, suppliers and other stakeholders. The risk assessments mentioning control measures is a further detailing of the concept of HACCP and the supporting Prerequisite Programmes as mentioned in chapter 5 and 6 of the accompanying European Code for the industrial manufacture of safe feed ingredients.

EBB would like to emphasize that companies remain primarily responsible for supplying safe feed and that this risk assessment cannot replace any responsibility.

**List of Abbreviations**

FAME: Fatty Acid Methyl Ester  
FAE: Fatty Acid Ester  
FFA: Free Fatty Acid  
MONG: Matter Organic Non Glycerol
2. Listing of feed ingredients

The main raw materials processed by the EU Biodiesel industry are crude or refined rapeseed oil, soybean oil, sunflower seed oil and palm oil in combination with methanol.

The Catalogue of the European Union for Feed Materials provides a common system in the EU for the description and labeling of feed ingredients. The Catalogue includes, for each feed ingredient listed, the name of the product, an identification number, a description of the feed ingredient including - if appropriate - information on the manufacturing process, and the particulars replacing the compulsory declaration for the purpose of article 16 (1) (b) of Regulation (EC) No 767/2009.

Hereby listed the biodiesel related feed ingredients within Reg. 68/2013/EU (adapted for vegetable origin):

<table>

</tr>
</tbody>
</table>
3. Process Description of Biodiesel

Biodiesel consists of Fatty Acid Methyl Esters and is produced by the chemical reaction of Oils and Fats with mono-alcohols, typically methanol. A catalyst, usually sodium or potassium hydroxide and/or methylate, is utilized to accelerate the formation of alkyl esters. This production process is generally known as transesterification.

### Vegetable Oils*
- Rapeseed Oil
- Soybean Oil
- Sunflower Seed Oil
- Palm Oil

### Alcohol*
- Methanol
- Ethanol

### Catalyst*
- Sodium hydroxide
- Potassium hydroxide
- Methylate

### Processing aids possibly used during treatment and processing*
- Water
- Aluminium Sulphate
- Citric Acid
- Potassium Hydroxide
- Sodium Hydroxide
- Sulphuric Acid
- Phosphoric Acid
- Hydrochloric Acid

*This list is non-exhaustive

This section will describe the process of biodiesel production from vegetable oils where the triglyceride oil is broken into alkyl (biodiesel) and glycerine by reaction with a mono alcohol. The biodiesel and glycerine phases are then separated and purified. Production processes contain the same stages, irrespective of the production scale, although the differences in equipment may be significant.

3.1. Reception of Vegetable Oil

Vegetable oils delivered to biodiesel plants are crude or refined vegetable oils. Pre-delivery (as per FEDIOL sector reference document) vegetable oils undergo a number of refining steps to remove various impurities, such as phosphatides, free fatty acids, traces of heavy metals, waxes, tocopherols or colorants, which could impede the biodiesel process reaction and biodiesel quality.

---

Most if not all vegetable oils undergo some form of pre-treatment for impurities or free fatty acid (FFA) reduction prior to being utilised as a raw material in the manufacture of biodiesel.

On delivery, the crude or refined vegetable oils are segregated to pre-processing storage tanks. The safety and quality of the incoming material is assessed in line with the EFISC incoming material requirements (Code §4.3.2).

It should be noted, depending on the biodiesel plant design and organisation, the safety and quality assessment of oils may also occur at an earlier stage (i.e. in cases of integrated plants (crushing/refining/esterification).

The content of free fatty acids, water and non-saponifiable substances are key parameters in achieving high conversion efficiency in the transesterification reaction. The results of the oils parameters will influence the quantity of raw material, alcohol and catalyst ratio in the transesterification process.

### 3.2. Reaction Stage/ Transesterification:

The objective of the reaction stage is to convert the free fatty acid (FFA) fraction of the feedstock into biodiesel. When the FFA content is high the reaction stage is usually conducted in two steps: esterification and transesterification.

Following the pre-processing analysis of the incoming vegetable oil, the alcohol and catalyst is mixed and sent to the reaction vessel where upon the vegetable oil is added (Figure 1 Flow Chart). This stage is known as esterification and is generally a pretreatment step to the transesterification which reduces the FFA content of the oil. The complete transesterification process is closed to the atmosphere to prevent any loss of alcohol. Excess alcohol is normally used to ensure total conversion of the oil to its esters.

### 3.3. Separation Stage

Once the reaction is complete, two major products exist: glycerine and biodiesel. Each has a substantial amount of the excess methanol that was used in the reaction. The reacted mixture is sometimes neutralized at this step if needed. The glycerine phase is much more dense than the biodiesel phase and the two can be gravity separated with glycerine simply drawn off the bottom of the settling vessel. In some cases, a centrifuge is used to separate the two materials faster.

### 3.4. Acidulation and FFA separation

Typically, the glycerine after the separator is usually 35% glycerine, 30% methanol, 25% water and 10% soap and catalyst. The catalyst is neutralized and soaps are split to free fatty acids and salts. Free fatty acids and methanol are removed and recovered.

### 3.5. Glycerin neutralization

The glycerine by-product contains unused catalyst and soaps that are neutralized with an acid and sent to storage as crude glycerine. In some cases the salt formed during this phase is recovered for use as fertilizer. If so water

*EFISC Code- Sector reference document on the manufacturing of safe feed ingredients from biodiesel processing, version 2.0*
and alcohol are removed to produce approx. 80% pure glycerine that is ready to be sold as crude glycerine.

3.6. Methyl Ester Wash

Once separated from the glycerine, the biodiesel is sometimes purified by washing gently with warm water to remove residual catalyst or soaps, than dried and sent to storage. In some processes this step is unnecessary.

3.7. Glycerine Refinery

Crude glycerine (Reg. 68/2013/EU; Chapter 13.8.1) can be further purified by a series of process steps (see below) for obtaining refined glycerine by removing water, salts, traces of MONG, color bodies and odors. A glycerine refinery broadly involves three processes (i) drying (ii) distillation and (iii) bleaching.

(i) Crude glycerine is transferred to a drying column and subsequently the de-watered crude glycerine is transferred to at least one desalting unit (distillation, decanting).
(ii) Distillation consists of vaporization, stripping and scrubbing of the glycerine phase; decanting consists of precipitation and removal of salts by settlement.
(iii) Final purification section uses deodorization and activated carbon to remove color and odor and other volatiles.

Refined Glycerine (Reg. 68/2013/EU; Chapter 13.8.2) can be delivered for feed ingredient but is mainly used for other applications (i.e. technical, pharmaceutical and cosmetic applications and food additive).

3.8. Storage

Glycerine is stored in suitable storage tanks (in line with the requirements as described in the FEDIOL sector document and EFISC Code).

3.9. Transport

The transportation of the glycerine has to be in line with EU and National legalisations, the EFISC Code, customer requirement and the requirements in this code ‘Sector reference document on the manufacturing of safe feed materials from biodiesel processing’.
4. Biodiesel Production Process Flow Chart

*This chart describes a general biodiesel process*
5. Risk Assessment

5.1. EBB made the following incoming materials subject to feed safety chain risk assessment

Raw Material: Vegetable Oils

In all cases, biodiesel sites are expected to comply with the requirements concerning HACCP implementation including risk assessments. A table of hazards is included in Appendix 1 but individuals should note that this list is not exhaustive and the operator should carry out their own risk assessments. Further information on specific hazards and control measures can be found in relevant HSE publications and EC Regulations in the Risk Assessment tables.

5.2. Summary of the risk-based approach for the biodiesel sector

In establishing the list of potential hazards, an operator should take due consideration of:

- The Regulation on genetically modified food and feed (1829/2003/EC).
- The Placing on the market Regulation (767/2009/EC)
- Laying down requirements for feed hygiene (183/2005/EC)
- The Regulation on maximum residues levels of pesticides in or on food and feed of plant and animal origin (396/2005/EC).
- The Regulation Catalogue of Feed Materials (68/2013/EU).

See EFISC Code chapter 7 Reference documents

The following list of examples is non-exhaustive and should be adapted according to the circumstances.

Biological hazards

- Relevant Vegetative Pathogens according to the feed hygiene regulation (183/2005/EC) and associated microbiological criteria.

Potential Chemical hazards*

- Process chemicals, processing aids and antioxidants,
- Mycotoxin
- Heavy metals
- Pesticides residues
- PCB, Dioxins
- Polycyclic aromatic hydrocarbons (PAH)
- Lubricants and mineral oils
Pest control chemicals

*This list is not exhaustive

The use of processing aids is included in the hazards analysis developed by the operator according to the requirements of the section 6 of the EFISC Code.

**Physical contamination hazards**

- Physical contamination, e.g. metal, glass, **plastics**

### 5.3. Risk-based approach for the characterisation of hazards applicable to feed materials coming from biodiesel production

The following tables present the characterisation of hazards applicable to products, coming from biodiesel production, sold as feed materials. For more understanding of the following risk assessment tables please see EFISC main text, chapter 6 HACCP system.

Those risks cannot be considered as complete and may differ amongst biodiesel producers based on individual and specific manufacturer’s processing conditions.

Biodiesel manufacturers have refined the risks to a level appropriate to their specific operating conditions.

Three categories of hazards were considered:

- Biological hazards;
- Chemical hazards; and,
- Physical hazards.
5.4. Procedure of carrying out risk assessment

EBB followed the methodology as described in the EFISC Code – chapter 6 – HACCP

5.4.1. Biodiesel Process: EBB constructed a flow chart covering all stages of biodiesel production: from transport and reception of raw materials, storage, application of processing aids, separation of materials following transestification, washing, further refining of glycerine, to the end product which is biodiesel and crude or refined glycerine feed ingredient, storage and transport.

5.4.2. For processing steps: utilities-related hazards were commonly described. A safety hazard is a biological (B), chemical (C) or physical agents (P) in, or condition of, a product that makes it injurious to human or animal health.

5.4.3. In the elements of the chain that directly relate to the professional activity of the EBB members within the production process a risk based assessment per hazard was conducted.

5.4.4. As previously described, those risks cannot be considered as complete and may differ amongst biodiesel producers based on individual and specific manufacturer’s processing conditions

Moreover, in these tables, no operational prerequisite programme (OPRP) or critical control point (CCP) is listed due to the fact that the decision leading to the establishment of such OPRP or CCP should be consistent with the actual operating conditions in each plant or processing line.

5.4.5. EBB justified the risk assessment

5.4.6. EBB checked whether EU legislation or trade standards sets limits for the respective hazard, and if so, listed them

**EFISC Code 4.2.3.2. Requirements for loading, storage, production areas and other feed ingredient related facilities**
Operator should conduct a risk assessment to control foreign bodies. Use of a filter/sieve during loading/unloading.
7. Minimum Monitoring

EFISC system participants shall implement a monitoring plan as described in the EFISC Code §4.4.3.

In case insufficient data is available for a risk assessment the following minimum monitoring requirements shall apply. The minimum number of analysis will depend on the volume of feed materials in tons manufactured in one location as shown in the table below.

**Minimum Monitoring plan Glycerine as by-product of the processing of vegetable oil**

**Table A  Glycerine and Crude Glycerine.**
